## About Me

- ▶ Yoav Palti, B.Sc in Aerospace Engineering, Technion, 2012
- ▶ Aeronautical algorithms engineer, IAF, since 2013
- ▶ M.Sc student since 2014

# Motivation

- ▶ Covering an area - (relatively) easy

# Motivation

- ▶ Covering an area - (relatively) easy
- ▶ Covering an area with not sufficient amount of sensors - not so easy
  - ▶ *Requires better definition of behaviour*

# Motivation

- ▶ Covering an area - (relatively) easy
- ▶ Covering an area with not sufficient amount of sensors - not so easy
  - ▶ *Requires better definition of behaviour*
- ▶ Maintain contact with home base (at least in steady state) - hard

# Problem Formulation

- ▶ There is some area  $A \in \mathbb{R}^2$  That we aim to cover
- ▶ We have set of sensors  $S = \{s_1 \dots s_n\}$  located in positions  $p_i \in \mathbb{R}^2$  (for  $i = 1, \dots, n$ ) at time  $t$ 
  - ▶ Each sensor has coverage radius  $R$  (assuming all sensors are identical)
  - ▶ Each sensor can cover a disk  $D(p_i(t), R) \subset \mathbb{R}^2$ , centred at  $p_i(t)$
- ▶ Thus, the coverage:

$$D(p_i(t), R) = D_i(t) = \{x \in \mathbb{R}^2 \mid \|x - p_i(t)\|_2 \leq R\}. \quad (1)$$

- ▶ We also assume  $D_i(t) \subset A$

## Problem Formulation

Coverage Constraint:

- ▶ A given area inside the area  $A_m \subset A$  must be covered always (e.g. ground station).

*A configuration:* A configuration  $c$  at time  $t$  is the stack of the sensor positions at time  $t$ ,

$$c(t) = \begin{bmatrix} p_1^T(t) & \cdots & p_n^T(t) \end{bmatrix}^T \in \mathbb{R}^{2n}. \quad (2)$$

### Notice

Since  $D_i(t) < A$ , there is no one configuration that can cover the entire area  $A$  at once

## Problem Formulation

Our goal is to find the set of configuration  $C$  which contains configurations that all together provide full coverage of the area  $A$ , and yet maintains the coverage of  $A_m$ .

### Problem

Find the set  $C = \left[ c_1^T(t_1) \quad \cdots \quad c_n^T(t_n) \right]^T$  that provide coverage at time  $i$  to some area  $A_c(t_i)$ , such that:

1. after time  $n$ , each point of  $A$  was visited at least once,
2. At each time there was coverage to some area  $A_{sm} \subset A_m$ .

# Lyapunov Stability

# Voronoi Partitioning

Let's start with a simple intuitive explanation...

## Voronoi Partitioning

While being a method to partition an area with some cost function, the is a widely-used representation in the coverage problem <sup>1 2 3</sup>.

# Voronoi Partitioning

The Voronoi Diagram of a region  $\Omega \subset \mathbb{R}^2$  is the set of partitions

$\mathcal{V} = \{V_i \mid \cup V_i = \Omega\}$ , generated by the generators

$\mathcal{Z} = \{z_1, \dots, z_n \mid z_i \in \Omega\}$ , such that

$$V_i = \{q \in \Omega \mid \|q - z_i\| \leq \|q - z_j\| \forall z_i, z_j \in \mathcal{Z}\}, \quad (3)$$

where  $V_i$  corresponds to the  $i$ -th element of  $\mathcal{Z}$ , and  $\|\cdot\|$  denotes the Euclidean distance.

## Central Voronoi Tessellations

And yet again, let's have an intuitive explanation...

## Central Voronoi Tessellations

Let us define a density function,  $\rho_i$ , for each Voronoi partition  $V_i$ . Then, we can define the center of mass for each partition as

$$z_i^* = \frac{\int_{V_i} y \rho(y) dy}{\int_{V_i} \rho(y) dy}. \quad (4)$$

If a generator  $z_i = z_i^* \forall V_i$ , we call this partitioning a *centroidal Voronoi tessellation* (CVT).

## Lloyd's Algorithm

Now that we know what Central Voronoi Tessellations are, we need to know how to calculate them.

Stuart P. Lloyd, an Electrical Engineer, invented an algorithm that deals with PCM quantization <sup>4</sup>.

It appears that the algorithm is very useful for calculating CVT's. Moreover, It is possible to build a controller based on this algorithm.

# Lloyd's Algorithm

---

**Algorithm 1** Lloyd's Algorithm

---

- 1: Calculate the Voronoi diagram for the current agents positions.
  - 2: Calculate the center of mass for every cell.
  - 3: Move the agents to the center of mass.
- 

According to Cortes et al., if we define agent  $i$  position as  $p_i$  and the  $i$ 's partition centroid as  $C_{V_i}$ , then for some proportional constant  $k_{prop}$ , the controller can be defined as:

$$u_i = -k_{prop} (p_i - C_{V_i}) \quad (5)$$

# Formation Control

# Projection Operator

The projection linear operator is defined as a linear transformation  $P$  from a vector space to itself such as  $P^2 = P$ . In other words, the transformation  $P$  is idempotent.
